## Alcohols: Reactions

The alcohol functional group is -O-H and its reactions involve cleavage of the O-H bond or the C-O bond —

In either case, there can be a subsequent substitution, or an elimination to form a double bond ---

Alcohols As Acids — Acidity is the result of the electronegativity of oxygen: R = O = H  $R = O + H^+$ 

Alcohols react with active metals:

 $R - O - H + Na \longrightarrow R - O Na^+ + 1/2 H_2$ 

| Acidity of Alcohols, | Compared to | Other Compounds: |
|----------------------|-------------|------------------|
|----------------------|-------------|------------------|

| Compound                 | рК <sub>а</sub> | Compound                                   | pKa   |
|--------------------------|-----------------|--|-------|
| HSO₄H                    | -10             | ArO <b>H</b>                               | 8-11  |
| HCI                      | -7              | HOH  | 15.74 |
| ArSO₃ <b>H</b>           | -6.5            | H  | 16    |
| RCH₂-HO <b>H</b> ⁺       | -2              | RCH₂O <b>H</b>                             | 18    |
| H₂O <b>H</b> ⁺           | -1.74           | н−с≡с− <b>н</b>                            | 25    |
| <b>H</b> NO <sub>3</sub> | -1.4            | H <sub>2</sub> N <b>H</b>                  | 34    |
| HF                       | 3.17            | CH <sub>2</sub> =HC <b>H</b>               | 36.5  |
| Ar-H₂N <b>H</b> ⁺        | 3-5             | Ph- <b>H</b>                               | 37    |
| RCOOH                    | 4-5             | CH <sub>3</sub> -H <sub>2</sub> C <b>H</b> | 42    |
| H₃N <b>Ħ</b> ⁺           | 9               | Ш.н.                                       | 100   |

Relative Acidities of Alcohols and Water:

| <u>pK</u> a |
|-------------|
| 15.7        |
| 15.5-16     |
| 16-18       |
| 18          |
| 19          |
|             |

Is this order the result of destabilization of alkoxide anion by alkyl group electron releasing inductive effect? Relative Gas Phase Acidities of Alcohols and Water:

 $(CH_3)_3COH > (CH_3)_2CHOH > CH_3CH_2OH > CH_3OH > H_2O$ 

Explanation — Solvation of anions:  $CH_3 > 1^\circ > 2^\circ > 3^\circ$ .

Alkoxide Anions Interact With Water

Reactions of Alcohols with H-X —

R-OH + HX (dry gas, conc. aq. soln.)  $\longrightarrow$  R-X + H<sub>2</sub>O

Reference acid catalyzed — eg addition of  $H_2SO_4$  increases rate; Lewis acids are also effective:

IS The alkyl group may rearrange, except for most 1° alcohols:

Solution  $\mathbb{R}^{\circ}$  Order of reactivity of R-OH: benzyl, allyl>3°>2°>1°<CH<sub>3</sub>. **Mechanism** 

Acid catalysis suggests protonation:

$$\mathbf{R}\text{-}\mathbf{OH} + \mathbf{HX} = \mathbf{R}\mathbf{OH}_2 + \mathbf{X}$$

Rearrangement (except for 1° R-OH) and reactivity order (except for  $CH_3OH$ ) suggest carbocation intermediates (except for  $CH_3OH$  and 1° R-OH), *ie*  $S_N1$ :

 $\stackrel{\bigoplus}{\text{ROH}_2} \xrightarrow{\bigoplus} \stackrel{\bigoplus}{\text{R}} + \text{OH}_2, \quad \stackrel{\bigoplus}{\text{R}} + \stackrel{\bigcirc}{\text{X}} \longrightarrow \text{R-X}$ 

Most 1° alcohols and methanol, on the other hand, react via the  $S_N 2$  mechanism of the **protonated** alcohol (OH<sup>-</sup> is a poor leaving group):

$$R-OH + H \xrightarrow{\bigoplus} ROH_2, ROH_2 + X \xrightarrow{\bigoplus} R-X + OH_2$$

## Summary ----

| Generally S <sub>N</sub> 1  | Generally S <sub>N</sub> 2  |
|---|---|
| benzyl, allyl, $3^{\circ}$ , $2^{\circ}$<br>favored by formation of<br>stable carbocation. $S_{N}2$ | 1°, CH <sub>3</sub> OH<br>favored by steric reasons.<br>$S_N$ 1 disfavored owing to |
| disfavored for steric   | generation of unstable  |
| reasons for 3°, 2°.   | carbocation.  |

Tertiary alcohols<br/>can be<br/>converted into<br/>halides by<br/>reaction withO<br/> $ROH + CISCI \longrightarrow RCI + HCI + SO_2$ <br/> $ROH + PBr_3 \longrightarrow RBr + HOPBr_2$ With<br/>HX. For primary

and secondary alcohols better results are often obtained by reacting the alcohol with  $PBr_3$  or  $SOCl_2$ . These reagents convert the -OH into a good leaving group which is displaced by halide ion in an  $S_N 2$  reaction.

Oxidation of Alcohols ---

Primary alcohols can be oxidized to aldehydes (with care) and carboxylic acids.

$$\operatorname{RCH}_{2}\operatorname{OH} \xrightarrow{\operatorname{K}_{2}\operatorname{Cr}_{2}\operatorname{O}_{7}} \xrightarrow{\operatorname{O}} \operatorname{RCOH}^{O}$$

Carboxylic Acids ---This oxidation occurs in two stages; there is an aldehyde intermediate,

but aldehydes are usually more easily oxidized than alcohols (many aldehydes are oxidized by air) and under the conditions of the reaction the aldehyde is not isolated.

Aldehydes --- This reaction is successful under certain carefully controlled conditions.

$$\begin{array}{c} & \bigoplus \\ \text{RCH}_2\text{OH} \xrightarrow{\begin{array}{c} \bigcirc \\ C_5\text{H}_5\text{NH} \end{array}} \xrightarrow{\begin{array}{c} \bigcirc \\ \text{CrO}_3\text{Cl} \end{array}} \xrightarrow{\begin{array}{c} \bigcirc \\ \text{RCH} \end{array}} \xrightarrow{\begin{array}{c} O \\ \text{RCH} \end{array}} \\ \text{RCH} \end{array}$$

Secondary alcohols can be oxidized to ketones.

$$R \stackrel{R'}{\xrightarrow{}}_{H} OH \xrightarrow{KMnO_4 \text{ or } CrO_3}_{Or \ K_2Cr_2O_7} R \stackrel{R'}{\xrightarrow{}} R \stackrel{R'}{\xrightarrow{}}_{H} OH$$

Further oxidation does not take place because it would involve

breaking a carbon-carbon bond.

Tertiary alcohols are not oxidized under basic conditions and are converted to alkenes under acidic conditions. [Alkenes may react with oxidizing agents.]

Grignard Synthesis of Alcohols

For example, starting with hydrocarbons or any aromatic compound containing 6 or fewer carbons synthesize the boxed compound below —
